Introduction

中国科学院植物研究所
INSTITUTE OF BOTANY, THE CHINESE ACADEMY OF SCIENCES

Rare species account for 30-60% of species richness in temperate and tropical forest plots

Introduction

Mechanical explanation:

spatial niche difference:

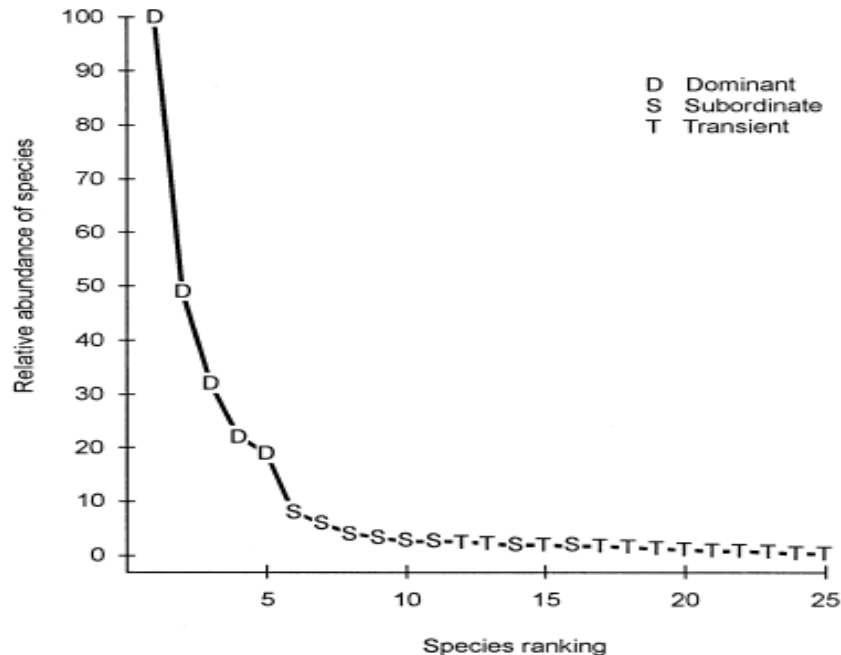

Niche position hypothesis (Gaston, 1994);

Dominants-subordinates-transients hypothesis
(Grime, 1998);

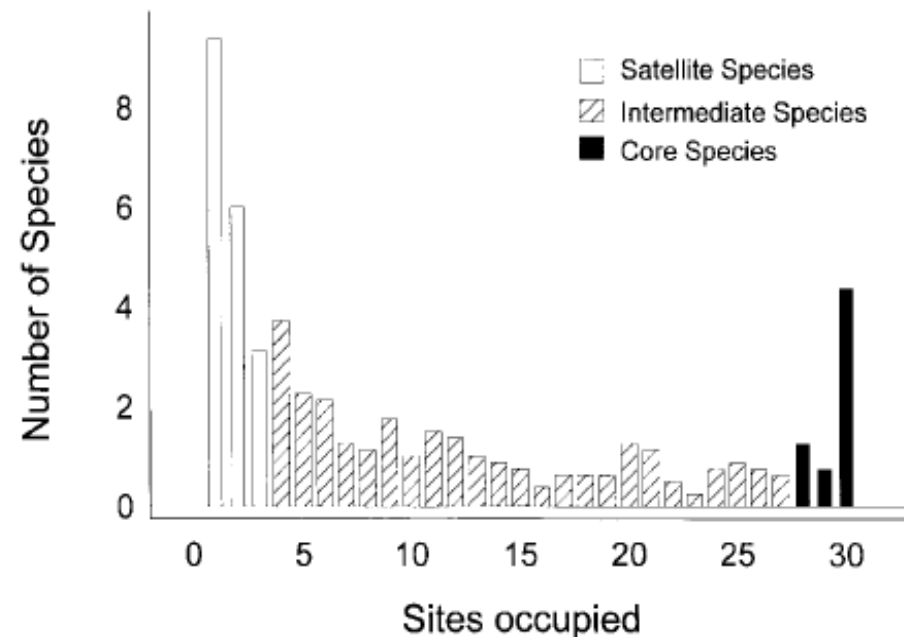

Core-satellite species hypothesis (Hanski, 1982,1991);

中国科学院植物研究所
INSTITUTE OF BOTANY, THE CHINESE ACADEMY OF SCIENCES

From Grime, 1998, J. Eco., 86:902

From Gibson, 1999, J. Eco., 87:1064

Introduction

Mechanical explanation:

Temporal niche difference: Storage effect (Chesson, 2000;
Kelly et al. 2001)

Neutral theory: Resource randomly assigned;

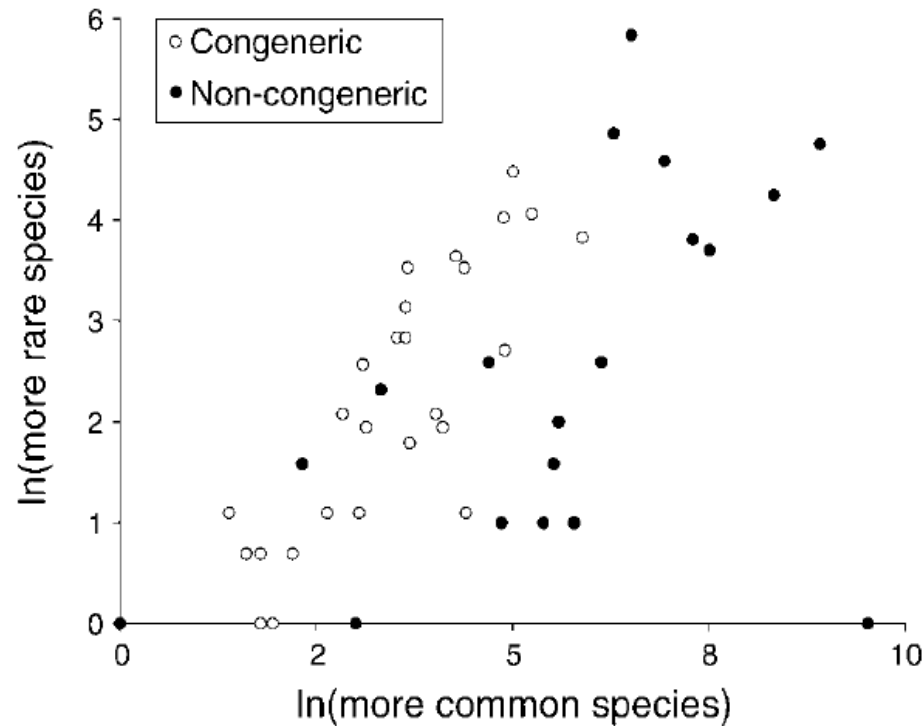

But testing these hypotheses is a methodological challenge:

1. Niche differentiation could be an artifact when the examined species exclude each other competitively from parts of their fundamental niches in natural communities;
2. Controlled experiments simplifies the environmental conditions and ‘similar’ niches in laboratory conditions may neglect multidimensional requirements of species niches;

Phylogenetic distance-good substitute

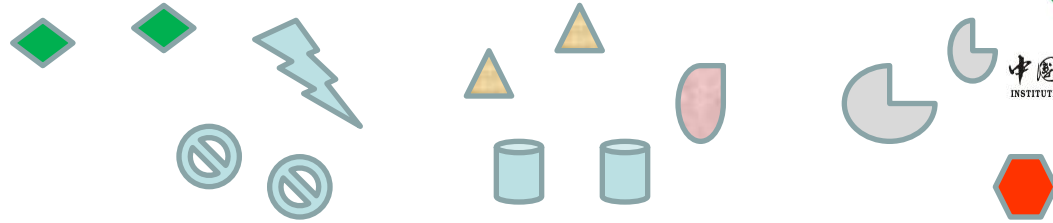

中国科学院植物研究所
INSTITUTE OF BOTANY, THE CHINESE ACADEMY OF SCIENCES

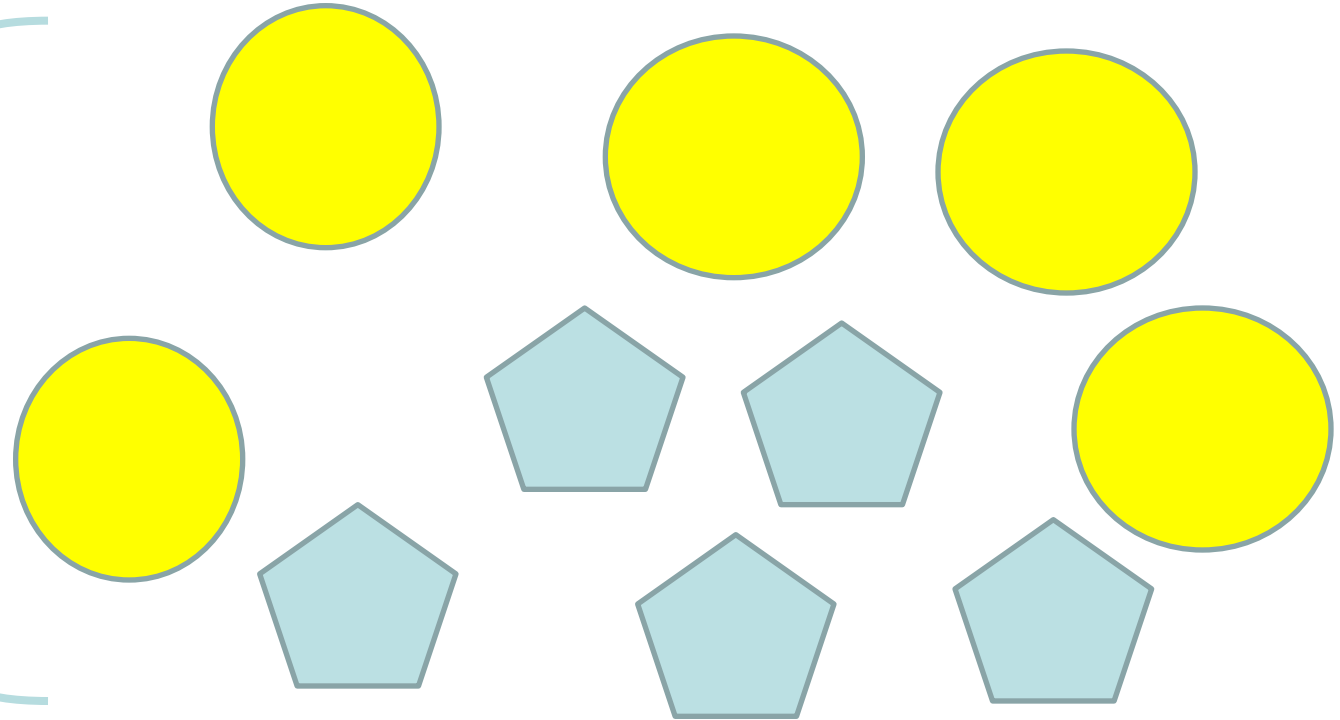

Kelly et al., 2008

Kelly et al. (2008) found that abundance of trees is closely correlated with phylogenetic distance in a Mexican forest; Anderson et al. (2004) found that species abundance in yeast community also correlated with its genetic relatedness.

**Rare
resource**

**Abundant
resource**

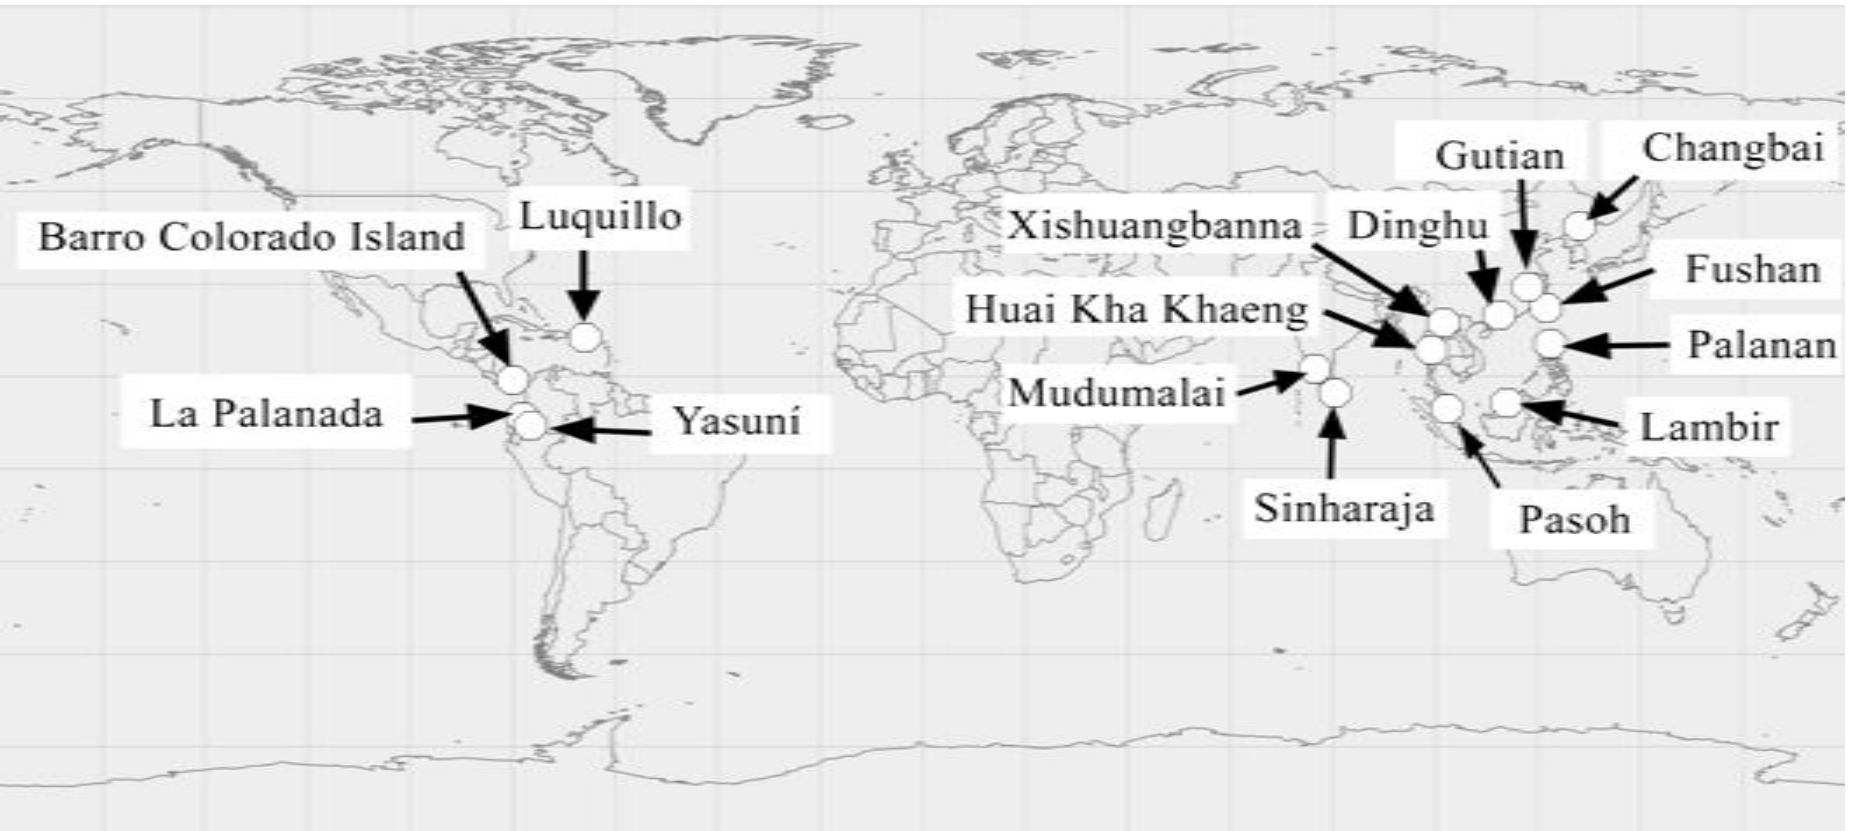

Following niche differentiation hypotheses, abundant species are distantly related to rare species, and rare species are distantly related to one another.

Niche differentiation hypothesis predicts:

- 1) Rare species contribute more to the community phylogenetic diversity;**
- 2) There is phylogenetic signal in abundance of communities;**
- 3) Rare species would be dissimilar with common species, and rare species should be dissimilar with one another.**

2. Methods: CTFS plots

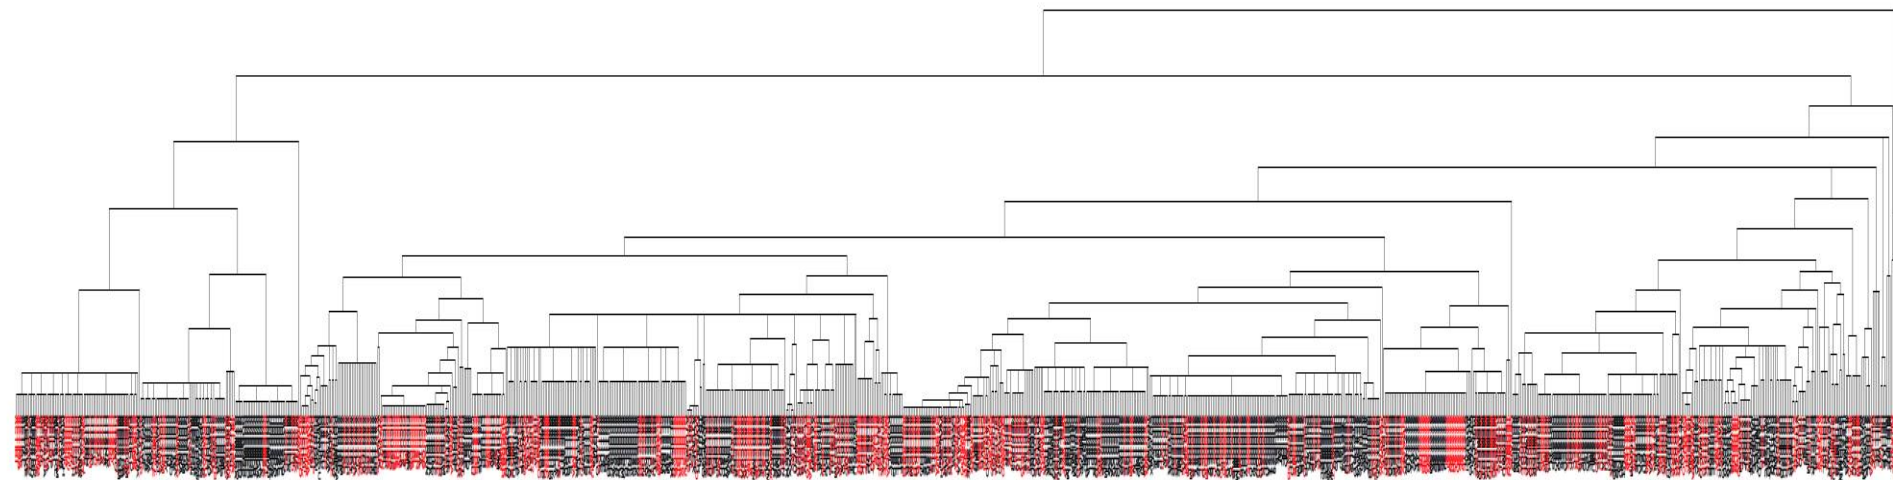

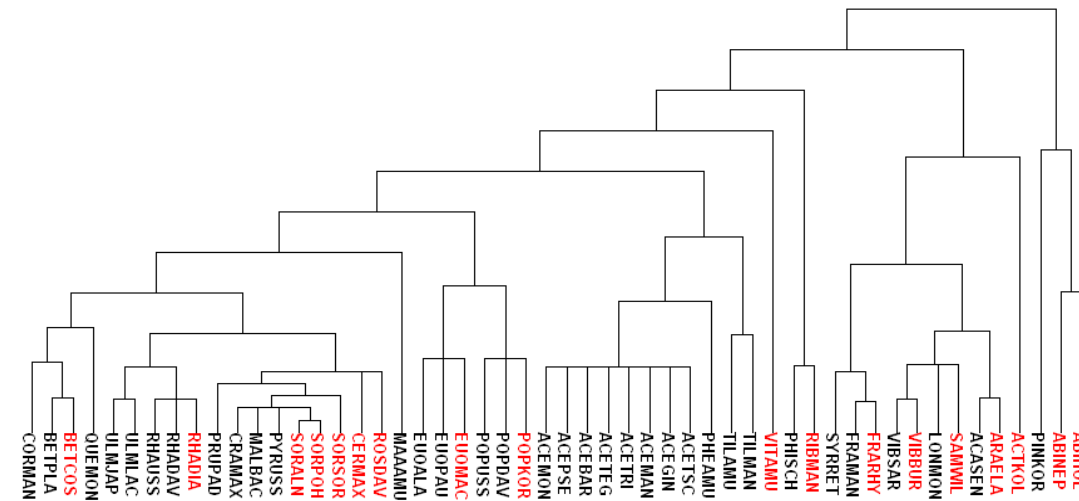

Methods:

1. Phylogenetic trees were constructed using phylomatic under APG III.

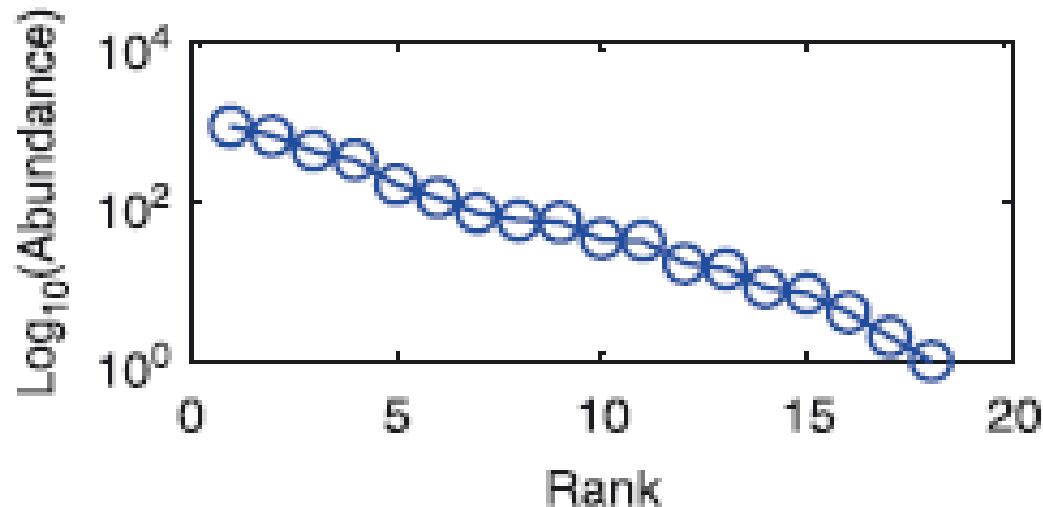

中国科学院植物研究所
INSTITUTE OF BOTANY, THE CHINESE ACADEMY OF SCIENCES

Tree of Changbai plot, with 52 species belonging to 32 genera, and Yasuni with 1045 species to 339 genera.

Methods

1) Species abundance rank - standardized phylogenetic diversity (SAPD) Curve:

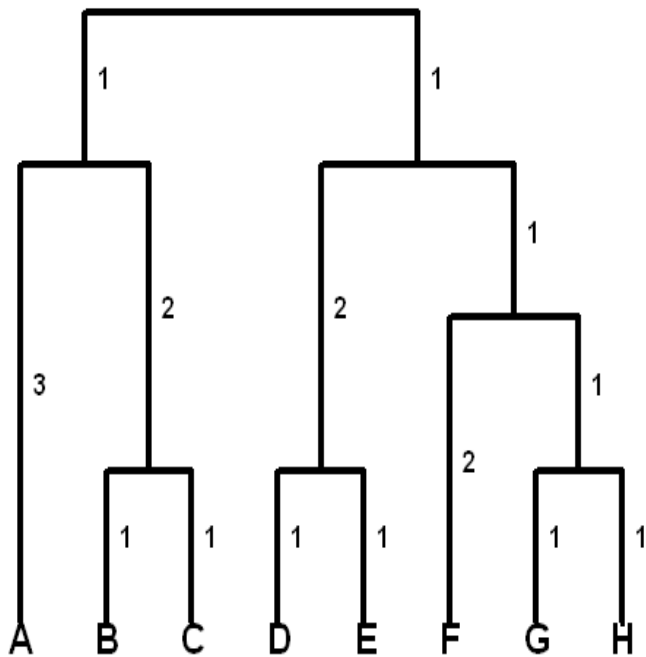

$$\text{StdPD}_i = \text{PD}_i - \text{mean}(\text{PD}_{\text{null}})$$

PD_i : standardized PD of the i th most abundant species;

Distant phylogenetic relatedness between common and rare species

INSTITUTE OF BOTANY, THE CHINESE ACADEMY OF SCIENCES

2) Piecewise regression

$$\text{stdPD}_i = \beta_0 + \beta_1 i + \sum_{j \geq 2} \beta_j (i - \alpha_j) I(i > \alpha_j)$$

stdPD_i is the value of stdPD for i th species rank, α_j is the j th breakpoint (the turning point between subseries), and the slopes of the lines are $\beta_1, \beta_1 + \beta_2, \dots$, and β_j is the difference in slopes, I is an indicator variable.

Methods:

3) Mann-Kendall trend test: test the increasing trend of *stdPD_i* along species rank.

4) Phylogenetic signal analysis of species abundance
Quantify phylogenetic signal using K statistics of Blomberg et al. (2003).

$$K = \text{observed} \frac{\text{MSE}_0}{\text{MSE}} \bigg/ \text{expected} \frac{\text{MSE}_0}{\text{MSE}}$$

If $K > 1$, the species abundance have more phylogenetic signal than expected under Brownian motion;

If $K < 1$, the species abundance have less phylogenetic signal than expected;

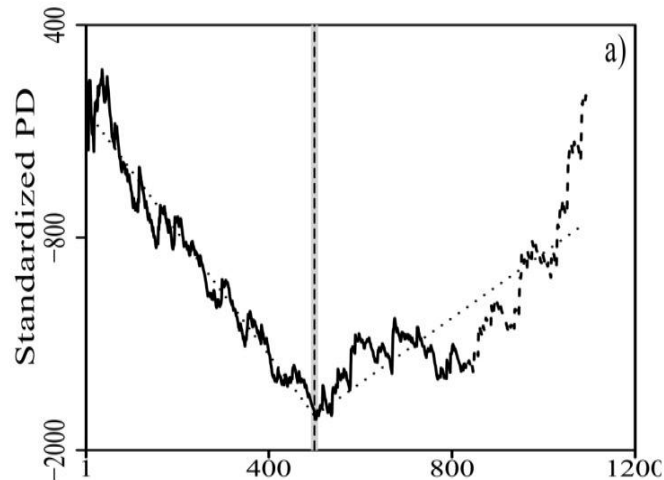

5) Nearest taxon index (NTI) was used to calculate phylogenetic dispersion of common and rare species.

$$D_{nn} = \frac{\sum_{i=1}^n \min \delta_{ir} + \sum_{j=1}^m \min \delta_{jc}}{2}$$

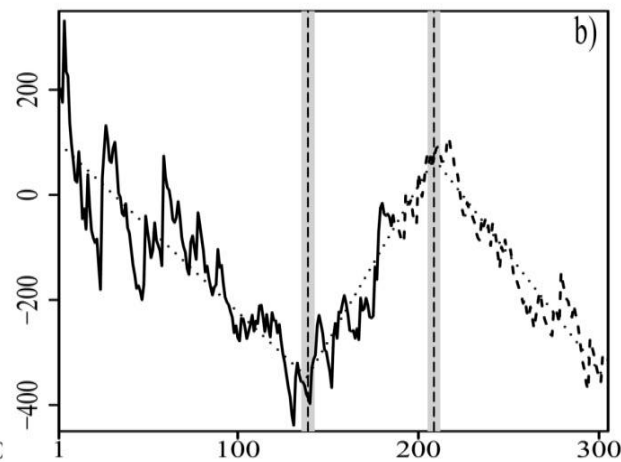

Results:

1. We detected three types of species rank-standardized phylodiversity curves (SAPD).

Mudumalai	-1.633	-.749	1.293
Luquillo	.325	1.018	-.354

Conclusions:

1. Rare species in Changbaishan, Gutianshan, Xishuangbanna, Pasoh, Lambir and Yasuní have significant higher cumulative PD than expected;
2. In BCI, the contribution of rare species to community PD is significantly less than expected;
3. In Dinghushan, Palanan, Luquillo, Fushan, Sinharaja, La Planada and Mudumalai, the contribution of rare species to community PD is not significantly different from random;
4. In HKK, some rare species contribute more and some rare species contribute less

The importance of being rare

Uncovering the contribution of rare species to ecosystems is crucial to predicting the impacts of biodiversity loss. It seems that these species can be ecologically very different from their common relatives, but only in some cases.

KEVIN J. GASTON

of these species will have few individuals, the number of rare species that are present^{2,3}. In

1. There was no reason to assume that all assemblages will be structured in generally the same way;
2. Their analysis did not address the influence of spatial scale on the observed ecological differentiation between rare and common species.
